

What is polymorphism and why is it important?

Polymorphism, like the other principles we've learned this semester, is an object-oriented principle. The principle allows the same method call to do multiple things if the object matches. In my recent goal setting project, the child classes SimpleGoal, EternalGoal and ChecklistGoal all inherited from the parent class Goal. In almost reverse fashion compared to inheritance, each child class had its own version of a similar method like my RecordEvent method. When the RecordEvent method was called, C# would use the correct method form the correct class. One of the greatest benefits of this Polymorphism is that it can reduce complicated code. Rather than running through lines and lines of checks to do the right thing, the class can just call the method, and the needed unique version of that method will be selected. This has the benefit of allowing me to change one functions of my program without affecting the others. This makes programs easier to read and easier to manage.
